## METHOD OF FORMING FLASH MEMORIES WITH HIGH COUPLING RATIO AND THE STRUCTURE OF THE SAME

The present invention relates to a semiconductor device, and more specifically, to a method of fabricating flash memories and the structure of the same.

## Background of the Invention

10 Various nonvolatile memories have been disclosed in the prior art. For example, Mitchellx has proposed EPROMs with self-aligned planar array cell. In this technique, buried diffusion self-aligned to floating gate avalanche injection MOS transistors are used for the bit lines. Cross point array technology 15 has been disclosed. The self-aligned source and drain will allow this device to be optimized even further for programming speed. See A. T. Mitchellx, "A New Self-Aligned Planar Cell for Ultra High 20 EPROMs", IEDM, Tech. pp. 548-553, 1987".

Flash memory is one of the segments nonvolatile memory devices. The device includes a floating gate to storage charges and an element for electrically placing charge on and removing charges from the floating gate. One of the applications of flash memory is BIOS for computer. Typically, the high-density nonvolatile memories can be applied as the mass storage of portable handy terminals, solid state camera and PC cards. That is because that the nonvolatile memories exhibit many advantages, such as a fast access time, low power dissipation, and robustness. Bergemont proposed

25

30

array for portable computing cell telecommunications application, which can be seen in Bergmont et al., "Low Voltage NVG™: A New High Performance 3 V/5 V Flash Technology for Portable Computing and Telecommunications Applications", Trans. Electron Devices, vol. ED-43, p. 1510, 1996. This cell structure is introduced for low voltage NOR Virtual Ground (NVG) flash memory having fast access time. In the flash array schematic, field oxides (FOX) are formed between cells such that a poly extension on FOX of each cell provides adequate gate coupling ratio. Bergmont also mentioned that the portable telecommunications and computing have become a major driving force in the field of integrated circuits. In the article, the access time is one of the concerns for low voltage read operation. array uses select devices to achieve a fast access time by reducing the pre-charge time to that of a single segment rather than the full bit-line.

15

The formation of nonvolatile memories toward the trends of low supply power and fast access, because these requirements are necessary for the application of the mobile computing system. Flash memory needs the charges to be hold in the floating gate for a long periods of time. Therefore, the dielectric that is used for insulating the floating gate needs to be high performance. At present, the low voltage flash memory is applied with a voltage of about 3V or 5V during charging or discharging the floating gate. As known in the art, tunneling is a basic technology in charging or discharging. In order to attain high tunneling efficiency, the thickness of the dielectric

between the floating gate and substrate have to be scaled down due to the supply voltage is reduced.

United States Patent No. 6,180,459 to Sheu, entitled "Method for fabricating a flash memory with shallow trench isolation", filed on January 8, 1999. The prior art disclosed a method for fabricating a flash memory comprising forming a shallow trench isolation (STI) structure is also formed in the method. A further United States Patent No. 6,172,395 to Chen, et al., entitled "Method of manufacture of self-aligned floating gate, flash memory cell and device manufactured thereby" and assigned to Taiwan Semiconductor Manufacturing Company (Hsin-Chu, TW).

15

A further prior article can be seen in United States Patent No. 6,171,909 to Ding, et al., entitled "Method for forming a stacked gate" and assigned to United Semiconductor Corp. (Hsinchu, TW) prior art is filed on April 16, 1999. The method 20 includes forming a first dielectric layer, conductive layer and a silicon nitride sequentially over a substrate. A photoresist pattern is formed over the silicon nitride layer. The silicon nitride layer, conductive layer, first dielectric 25 and substrate are etched by using photoresist pattern as an etching mask until forming plurality of trenches in the substrate. An insulating layer is formed over the substrate. A conductive spacer is formed on the sidewalls of the 30 conductive layer and silicon nitride layer, wherein the conductive spacer and conductive layer serve as a first gate conductive layer. The silicon nitride

layer is removed. A second dielectric layer and a second gate conductive layer are formed over the substrate. The second gate conductive layer, second dielectric layer and first gate conductive layer are patterned to form a control gate, a patterned dielectric layer and a floating gate, respectively.

## Summary of the Invention

The object of the present invention is to form a self-aligned floating gate with higher coupling ratio.

The further object is to form the floating gate and trench without switching the chamber.

The yet object of the present invention is to form the floating gate and trench, simultaneously.

present invention comprises forming tunneling dielectric layer on the substrate and a first conductive layer on the tunneling dielectric layer. Then, patterning the first polysilicon layer, 20 the tunneling dielectric layer and the substrate to form trenches therein before a gap-filling material is refilled into the trenches and over the substrate. A portion of the gap-filling material is removed to form trench isolations. A portion of the trench 25 isolations is etched to form slots between the etched first conductive layer. Next, a second conductive layer is formed over a surface of the slots and the etched first conductive layer. The second conductive layer is etched, thereby forming sidewall spacers on 30 the slot. Next step is to form a second dielectric layer on the trench isolation, the sidewall spacers and the first conductive layer; and forming a third

conductive layer on the second dielectric layer to act as a control gate.

The flash memory structure includes a substrate having trenches formed therein, a first dielectric layer and a first conductive layer are stacked on the substrate. Isolations are formed in the trenches and protruding over the surface of the substrate, wherein the first conductive layer is also protruded over the isolations. A second conductive layer is lying the surface of the first conductive layer and a second dielectric layer formed thereon. A third conductive layer is formed on the second dielectric layer. The floating gate is consisted of first conductive layer and the second conductive layer.

## Brief Description of the Drawings

The foregoing aspects and many of the attendant advantages of this invention will become more readily appreciated as the same becomes better understood by reference to the following detailed description, when taken in conjunction with the accompanying drawings, wherein:

Detailed Description of the Preferred Embodiment
The present invention proposes a novel method to
fabricate a flash nonvolatile memory. In the method,
trench and the floating gate are simultaneously
formed in one step. The structure can form selfaligned silicon island structure. During the
formation of trench, the substrate does not need to
be switched to another chamber due to the floating
gate and substrate are composed of identical material.
The detail description will be seen as follows.

25

5

10

The first embodiment of the structure, as shown in FIGURE 4, includes a substrate 2 having trenches formed therein, a first dielectric layer 4 and a first conductive layer are stacked on the substrate 2. 30 Isolations are formed 10 in the trenches protruding over the surface of the substrate 2. wherein the first conductive layer 6 protruded over the isolations 10. A second conductive

layer 14 is lying the surface of the first conductive layer 6 and a second dielectric layer 18 formed thereon. A third conductive layer 20 is formed on the second dielectric layer 18. The floating gate is consisted of first conductive layer 6 and the second conductive layer 18.

Alternatively, further sidewall spacers 16 are attached on the side wall of the floating gate consisting of first conductive layer 6 and the second dielectric layer 18, as shown in FIGURE 4A.

10

15

25

30

Another embodiment can be seen in FIGURE 4b, the second conductive layer 14 is omitted and the spacers 14a are attached on the floating gate consisting of first conductive layer 6 only. Yet another embodiment of the present invention is that even the spacers 14a are also abridged, referring to 5.

20 The processes for forming the devices are described as follows.

A semiconductor substrate is provided for the present invention. In a preferred embodiment, as shown in the FIGURE 1, a single crystal silicon substrate 2 with a <100> or <111> crystallographic orientation is provided. A thin tunneling dielectric layer 4 consisted of silicon oxide is formed on the substrate 2. Typically, the oxide 4 can be grown in oxygen ambient at a temperature of about 700 to 1100 degrees centigrade. Other method, such as chemical vapor deposition, can also form the gate oxide 4. In the embodiment, the thickness of the silicon dioxide

layer 4 is approximately 15-250 angstroms. Subsequently, a conductive layer such as doped polysilicon layer 6 or metal is deposited on the tunneling dielectric layer 4. Generally, the polysilicon layer 6 is chosen from doped polysilicon or in-situ polysilicon. For an embodiment, the doped polysilicon layer 8 is doped by phosphorus using a PH<sub>3</sub> source.

10 Next, still referring to FIGURE 1, standard lithography and etching steps are used to etch the polysilicon layer 6, tunneling dielectric layer 4 and into the substrate 2 to a depth to form trenches 8 in the substrate. In the step, the isolation area and 15 the floating gate 6 are simultaneously formed. This method provides self-aligned floating gate. In this case, the dry etching uses  $CF_4+O_2$  plasma. filling material 10, such as oxide formed by a CVD system, which is referred to as CVD-oxide, 20 refilled into the trenches 8 for isolation. Preferably, the oxide layer 10 is formed at a temperature in the range of about 400 to 600 degrees centigrade. A chemical mechanical polishing (CMP) technology is used to remove the top of the CVD-oxide 10 to the surface of the conductive layer 6. 25

Referring to FIGURE 3, an etching back process is performed to etch the oxide 10 using the high selectivity etching between oxide and silicon. The upper portion of the oxide 10 is removed to form slots 12 between the floating gates 10, and the depth of the slots 12 from the surface of the floating gate 10 ca be defined by the etching. A second conductive

30

layer 14 is conformally formed along the surface of the floating gate 6 and the slot 12. The conductive layer 6 and the second conductive layer 14 are combined to act as the floating gate. If the width of the first conductive 6 is x, the thickness of the second conductive layer 14 is Y, thus the upper surface area of the floating gate is approximately X+2Y. It can improve the coupling ratio. An etching is optionally used to etch the second conductive layer 14 to form spacers 14a on the side wall of the slot 12, as shown in FIGURE 3B.

Another embodiment is shown in FIGURE 3A, sidewall spacers 16 are formed in the slot 12 and attached on the sidewall of the second conductive layer 14. The sidewall spacers 16 are formed by well known anisotropically etching. Assume again that the thickness of the sidewall spacers 16 is Z, then the upper surface of the floating gate is about X+2Y+2Z.

20

25

30

10

15

Next, please turn to FIGURE 4-4B,an polysilicon dielectric (IPD) 18 is formed at the top of the floating gate. Preferably, the (oxide/nitride/oxide) or NO is used as the IPD 18. Finally, a third conductive layer 20, such as doped polysilicon layer or metal 16, is formed on the IPD 18 as control gate. The doped polysilicon layer 20 can be chosen from doped polysilicon or in-situ doped polysilicon. In addition, the metal or alloy layer can be used as the conductive layer 20.

Turning to FIGURE 5, alternatively, the dielectric layer may directly be formed 18 on the

surface of the etched first conductive layer 6, followed by forming the layer 20.

In the process of this invention, a tunnel oxide layer, floating gate and the trench are defined at the same time. Namely, the floating gate and tunnel oxide simultaneously are self-aligned formed adjacent to the shallow trench isolation. Further, the present invention provides a benefit of that the substrate does not need to be switched to another chamber during the trench etching due to the floating gate and substrate are composed of the same material.

As will be understood by persons skilled in the 15 art, the foregoing preferred embodiment of present invention is illustrative of the present invention rather than limiting the present invention. Having described the invention in connection with a preferred embodiment, modification will now suggest 20 itself to those skilled in the art. Thus, invention is not to be limited to this embodiment, but rather the invention is intended to cover various modifications and similar arrangements included within the spirit and scope of the appended claims, 25 the scope of which should be accorded the broadest interpretation so as to encompass all modifications and similar structures.

While the preferred embodiment of the invention 30 has been illustrated and described, it will be appreciated that various changes can be made therein without departing from the spirit and scope of the invention.
